Cinchona alkaloids represent a diverse class of naturally occurring compounds that have been extensively studied and utilized in various fields of chemistry and biochemistry over the past two centuries.<sup>1,2</sup> These versatile molecules have demonstrated a wide range of applications, including their use as chiral organocatalysts, ligands, chromatographic selectors, antimalarial drugs, and NMR discriminating agents.

Our research aims to further explore the potential of cinchona alkaloid-appended thiols with varying chain lengths ( $n = 0, 2, 4, \dots$ ) as chiral ligands in gold nanocluster chemistry, see figure. We plan to synthesize and incorporate these ligands into nanoclusters such as  $\text{Au}_{25}(\text{PET})_{18}$  through ligand exchange reactions (LER).<sup>3</sup> By introducing these chiral ligands, we aim to investigate their potential applications in enantioselective organocatalysis, NMR discrimination, and other related fields.<sup>4</sup>

In this poster presentation, we will showcase the synthesis of the alkaloid derivative and present its application as chiral ligand on atomically precise gold clusters.

**L1 ( $n = 0, 2, 4, \dots$ )**
